++ This domain represents univariate polynomials in some symbol
++ over arbitrary (not necessarily commutative) coefficient rings.
++ The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field, then this domain
++ forms a euclidean domain.

UnivariatePolynomial(x:Symbol, R:Ring):
  UnivariatePolynomialCategory(R) with
    coerce: Variable(x) -> %
      ++ coerce(x) converts the variable x to a univariate polynomial.
    fmeq: (% , NonNegativeInteger, R, %) -> %
      ++ fmeq(p1, e, r, p2) finds x : p1 - r * x**e * p2
  == SparseUnivariatePolynomial(R)    add
  Rep:=SparseUnivariatePolynomial(R)
  coerce(p:%):OutputForm == outputForm(p, outputForm x)
  coerce(v:Variable(x)):% == monomial(1, 1)

```

)abbrev domain UPXS UnivariatePuisseuxSeries
++ Author: Clifton J. Williamson
++ Date Created: 28 January 1990
++ Date Last Updated: 21 September 1993
++ Basic Operations:
++ Related Domains:
++ Also See:
++ AMS Classifications:
++ Keywords: series, Puiseux
++ Examples:
++ References:
++ Description:
++ Dense Puiseux series in one variable
++ \spadtype{UnivariatePuisseuxSeries} is a domain representing Puiseux
++ series in one variable with coefficients in an arbitrary ring. The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion. For example,
++ \spad{UnivariatePuisseuxSeries(Integer,x,3)} represents Puiseux series in

```

```

++ \spad{(x - 3)} with \spadtype{Integer} coefficients.

UnivariatePuisseuxSeries(Coef,var,cen): Exports == Implementation where
  Coef : Ring

)abbrev domain UPXSCONS UnivariatePuisseuxSeriesConstructor
++ Author: Clifton J. Williamson
++ Date Created: 9 May 1989
++ Date Last Updated: 30 November 1994
++ Basic Operations:
++ Related Domains:
++ Also See:
++ AMS Classifications:
++ Keywords: series, Puiseux, Laurent
++ Examples:
++ References:
++ Description:
++ This package enables one to construct a univariate Puiseux series
++ domain from a univariate Laurent series domain. Univariate
++ Puiseux series are represented by a pair \spad{[r,f(x)]}, where r is
++ a positive rational number and \spad{f(x)} is a Laurent series.
++ This pair represents the Puiseux series \spad{f(x^r)}.

=====
UnivariateSkewPolynomial examples
=====

```

Skew or Ore polynomial rings provide a unified framework to compute with differential and difference equations.

In the following, let A be an integral domain, equipped with two endomorphisms σ and δ where:

$\sigma: A \rightarrow A$ is an injective ring endomorphism
 $\delta: A \rightarrow A$, the pseudo-derivation with respect to σ ,
 is an additive endomorphism with

$$\delta(ab) = \sigma(a)\delta(b) + \delta(a)b$$

for all a, b in A

Note that in the domains and categories below, these properties are not checked.

The skew polynomial ring $[\Delta; \sigma, \delta]$ is the ring of polynomials in Δ with coefficients in A , with the usual addition, while the product is given by

$$\Delta a = \sigma(a)\Delta + \delta(a) \text{ for } a \text{ in } A$$

The two most important examples of skew polynomial rings are:

$K(x)[D, 1, \delta]$, where 1 is the identity on K and δ is the usual derivative, is the ring of differential polynomials

$K[E, n, \text{mapsto } n+1, 0]$ is the ring of linear recurrence operators with polynomial coefficients

For example,

The `UnivariateSkewPolynomialCategory` (`OREPCAT`) provides a unified framework for polynomial rings in a non-central indeterminate over some coefficient ring R . The commutation relations between the indeterminate x and the coefficient t is given by

$$x r = \sigma(r) x + \delta(r)$$

where σ is a ring endomorphism of R and δ is a σ -derivation of R which is an additive map from R to R such that

$$\delta(rs) = \sigma(r) \delta(s) + \delta(r) s$$

In case σ is the identity map on R , a σ -derivation of R is just called a derivation. Here are some examples

We start with a linear ordinary differential operator. First, we define the coefficient ring to be expressions in one variable x with fractional coefficients:

$$F := \text{EXPR}(\text{FRAC}(\text{INT}))$$

Define Dx to be a derivative d/dx :

$$Dx: F \rightarrow F: f \mapsto D(f, [x])$$

Define a skew polynomial ring over F with identity endomorphism as σ and derivation d/dx as δ :

$$D0 := \text{OREUP}('d, F, 1, Dx)$$

u:D0:=(operator 'u)(x)

d:D0:='d

a:D0:=u^3*d^3+u^2*d^2+u*d+1

$$u(x)^3 d^3 + u(x)^2 d^2 + u(x) d + 1$$

b:D0:=(u+1)*d^2+2*d

$$(u(x) + 1) d^2 + 2d$$

r:=rightDivide(a,b)

$$\begin{aligned} \text{[quotient= } & \frac{u(x)^3}{u(x)^3 + 1} d + \frac{-u(x)^3 u'(x) - u(x)^3 + u(x)^2}{u(x)^2 + 2u(x) + 1}, \\ & \frac{2u(x)^3 u'(x) + 3u(x)^3 + u(x)^3}{u(x)^2 + 2u(x) + 1} d + 1] \end{aligned}$$

r.quotient

$$\frac{u(x)^3}{u(x)^3 + 1} d + \frac{-u(x)^3 u'(x) - u(x)^3 + u(x)^2}{u(x)^2 + 2u(x) + 1}$$

r.remainer

$$\frac{2u(x)^3 u'(x) + 3u(x)^3 + u(x)^3}{u(x)^2 + 2u(x) + 1} d + 1$$

```
)clear all
```

As a second example, we consider the so-called Weyl algebra.

Define the coefficient ring to be an ordinary polynomial over integers in one variable t

```
R:=UP('t,INT)
```

Define a skew polynomial ring over R with identity map as $\backslash\sigma$ and derivation d/dt as $\backslash\delta$. The resulting algebra is then called a Weyl algebra. This is a simple ring over a division ring that is non-commutative, similar to the ring of matrices.

```
W:=OREUP('x,R,1,D)
```

```
t:W:='t
```

```
x:W:='x
```

Let

```
a:W:=(t-1)*x^4+(t^3+3*t+1)*x^2+2*t*x+t^3
```

$$(t - 1)x^4 + (t^3 + 3t + 1)x^2 + 2tx + t^3$$

```
b:W:=(6*t^4+2*t^2)*x^3+3*t^2*x^2
```

$$(6t^4 + 2t^2)x^3 + 3t^2x^2$$

Then

```
a*b
```

$$\begin{aligned} & (6t^5 - 6t^4 + 2t^3 - 2t^2)x^5 + (96t^4 - 93t^3 + 13t^2 - 16t)x^6 \\ & + (6t^7 + 20t^5 + 6t^4 + 438t^3 - 406t^2 - 24)x^5 \\ & + (48t^6 + 15t^5 + 152t^4 + 61t^3 + 603t^2 - 532t - 36)x^4 \\ & + (6t^7 + 74t^5 + 60t^4 + 226t^3 + 116t^2 + 168t - 140)x^3 \\ & + \end{aligned}$$

$$\begin{aligned}
& (3t^5 + 6t^3 + 12t^2 + 18t + 6)x^2 \\
a^3 & \\
& (t^3 - 3t^2 + 3t - 1)x^{12} + (3t^5 - 6t^4 + 12t^3 - 15t^2 + 3t + 3)x^{10} \\
& + (6t^3 - 12t^2 + 6t)x^9 + (3t^7 - 3t^6 + 21t^5 - 18t^4 + 24t^3 - 9t^2 - 15t - 3)x^8 \\
& + (12t^5 - 12t^4 + 36t^3 - 24t^2 - 12t)x^7 \\
& + (t^9 + 15t^7 - 3t^6 + 45t^5 + 6t^4 + 36t^3 + 15t^2 + 9t + 1)x^6 \\
& + (6t^7 + 48t^5 + 54t^3 + 36t^2 + 6t)x^5 \\
& + (3t^9 + 21t^7 + 3t^6 + 39t^5 + 18t^4 + 39t^3 + 12t^2)x^4 \\
& + (12t^7 + 36t^5 + 12t^4 + 8t^3)x^9 + (3t^9 + 9t^7 + 3t^6 + 12t^5)x^2 + 6t^7x + t^9
\end{aligned}$$

```
)clear all
```

As a third example, we construct a difference operator algebra over the ring of `EXPR(INT)` by using an automorphism `S` defined by a "shift" operation `S:EXPR(INT) -> EXPR(INT)`

```
s(e)(n) = e(n+1)
```

and an `S`-derivation defined by `DF:EXPR(INT) -> EXPR(INT)` as

```
DF(e)(n) = e(n+1)-e(n)
```

Define `S` to be a "shift" operator, which acts on expressions with the discrete variable `n`:

```
S:EXPR(INT)->EXPR(INT):=e+>eval(e,[n],[n+1])
```

Define `DF` to be a "difference" operator, which acts on expressions with a discrete variable `n`:

```
DF:EXPR(INT)->EXPR(INT):=e+>eval(e,[n],[n+1])-e
```

Then define the difference operator algebra D0:

```
D0:=OREUP('D,EXPR(INT),morphism S,DF)
```

```
u:=(operator 'u)[n]
```

```
L:D0:='D+u
```

$$D + u(n)$$

$$L^2$$

$$D^2 + 2u(n)D + u(n)^2$$

```
)clear all
```

As a fourth example, we construct a skew polynomial ring by using an inner derivation δ induced by a fixed y in R :

$$\delta(r) = yr - ry$$

First we should expose the constructor SquareMatrix so it is visible in the interpreter:

```
)set expose add constructor SquareMatrix
```

Define R to be the square matrix with integer entries:

```
R:=SQMATRIX(2,INT)
```

```
y:R:=matrix [[1,1],[0,1]]
      +1  1+
      |   |
      +0  1+
```

Define the inner derivative δ :

```
delta:R->R:=r+>y*r-r*y
```

Define S to be a skew polynomial determined by $\sigma = 1$ and δ as an inner derivative:

```
S:=OREUP('x,R,1,delta)
```

```
x:S:='x
```

```
a:S:=matrix [[2,3],[1,1]]
```

```

+2  3+
|    |
+1  1+

x^2*a
+2  3+ 2  +2  - 2+  +0  - 2+
|    |x  + |    |x  + |    |
+1  1+  +0  - 2+  +0  0  +

```

Vector examples

=====

The Vector domain is used for storing data in a one-dimensional indexed data structure. A vector is a homogeneous data structure in that all the components of the vector must belong to the same Axiom domain. Each vector has a fixed length specified by the user; vectors are not extensible. This domain is similar to the OneDimensionalArray domain, except that when the components of a Vector belong to a Ring, arithmetic operations are provided.

As with the OneDimensionalArray domain, a Vector can be created by calling the operation new, its components can be accessed by calling the operations elt and qelt, and its components can be reset by calling the operations setelt and qsetelt.

This creates a vector of integers of length 5 all of whose components are 12.

```

u : VECTOR INT := new(5,12)
[12,12,12,12,12]

```

Type: Vector Integer

This is how you create a vector from a list of its components.

```

v : VECTOR INT := vector([1,2,3,4,5])
[1,2,3,4,5]

```

Type: Vector Integer

Indexing for vectors begins at 1. The last element has index equal to the length of the vector, which is computed by #.

```
#(v)
5
```

Type: PositiveInteger

This is the standard way to use elt to extract an element. Functionally, it is the same as if you had typed elt(v,2).

```
v.2
2
```

Type: PositiveInteger

This is the standard way to use setelt to change an element. It is the same as if you had typed setelt(v,3,99).

```
v.3 := 99
99
```

Type: PositiveInteger

Now look at v to see the change. You can use qelt and qsetelt (instead of elt and setelt, respectively) but only when you know that the index is within the valid range.

```
v
[1,2,99,4,5]
```

Type: Vector Integer

When the components belong to a Ring, Axiom provides arithmetic operations for Vector. These include left and right scalar multiplication.

```
5 * v
[5,10,495,20,25]
```

Type: Vector Integer

```
v * 7
[7,14,693,28,35]
```

Type: Vector Integer

```
w : VECTOR INT := vector([2,3,4,5,6])
[2,3,4,5,6]
```

Type: Vector Integer

Addition and subtraction are also available.

```
v + w
[3,5,103,9,11]
```

Type: Vector Integer

Of course, when adding or subtracting, the two vectors must have the same length or an error message is displayed.

```
v - w  
[- 1,- 1,95,- 1,- 1]
```

Type: Vector Integer

=====
Void examples
=====

```

When an expression is not in a value context, it is given type Void.
For example, in the expression

```
r := (a; b; if c then d else e; f)
```

values are used only from the subexpressions c and f: all others are thrown away. The subexpressions a, b, d and e are evaluated for side-effects only and have type Void. There is a unique value of type Void.

You will most often see results of type Void when you declare a variable.

```

a : Integer
                                     Type: Void

```

Usually no output is displayed for Void results. You can force the display of a rather ugly object by issuing

```

)set message void on

b : Fraction Integer
                                     Type: Void

```

```
)set message void off
```

All values can be converted to type Void.

```
3::Void
```

```
Type: Void
```

Once a value has been converted to Void, it cannot be recovered.

```
% :: PositiveInteger
```

```
Cannot convert from type Void to PositiveInteger for value "()"
```

=====

WuWenTsunTriangularSet examples

=====

The WuWenTsunTriangularSet domain constructor implements the characteristic set method of Wu Wen Tsun. This algorithm computes a list of triangular sets from a list of polynomials such that the algebraic variety defined by the given list of polynomials decomposes into the union of the regular-zero sets of the computed triangular sets. The constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category IntegralDomain. The second one, E, is the exponent monoid of the

polynomials; it must belong to the category `OrderedAbelianMonoidSup`. The third one, `V`, is the ordered set of variables; it must belong to the category `OrderedSet`. The last one is the polynomial ring; it must belong to the category `RecursivePolynomialCategory(R,E,V)`. The abbreviation for `WuWenTsunTriangularSet` is `WUTSET`.

Let us illustrate the facilities by an example.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
OrderedVariableList [x,y,z,t]
Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
Type: Domain
```

Let the variables be polynomial.

```
x: P := 'x
x
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

y: P := 'y
y
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
```

```

z: P := 'z
z
Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

t: P := 't
t
Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

```

Now call the WuWenTsunTriangularSet domain constructor.

```

T := WUTSET(R,E,V,P)
WuWenTsunTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t]
,OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t]))
Type: Domain

```

Define a polynomial system.

```

p1 := x ** 31 - x ** 6 - x - y
31      6
x      - x      - x - y
Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

p2 := x ** 8 - z
8
x      - z
Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
10
x      - t
Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

lp := [p1, p2, p3]
31      6      8      10
[x      - x      - x - y, x      - z, x      - t]
Type: List NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

```

Compute a characteristic set of the system.

```

characteristicSet(lp)$T
5      4      4      2      2      3      4      7      4      6      6      3      3      3      3
{z      - t      , t z y      + 2t z y + (- t      + 2t      - t)z      + t z, (t      - 1)z x - z y - t }
Type: Union(WuWenTsunTriangularSet(Integer,

```

```

IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [x,y,z,t])),...)

```

Solve the system.

```

zeroSetSplit(lp)$T
      3      5      4      3      3      2
[[{t,z,y,x}, {t3 - 1, z5 - t4, z4 y + t3, z3 x - t2},
  {z5 - t4, t4 z y + 2t3 z y + (-t3 + 2t2 - t)z4 + t6 z, (t6 - 1)z3 x - z3 y - t3}]
Type: List WuWenTsunTriangularSet(Integer,
  IndexedExponents OrderedVariableList [x,y,z,t],
  OrderedVariableList [x,y,z,t],
  NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t]))

```

The RegularTriangularSet and SquareFreeRegularTriangularSet domain constructors, the LazardSetSolvingPackage package constructors as well as, SquareFreeRegularTriangularSet and ZeroDimensionalSolvePackage package constructors also provide operations to compute triangular decompositions of algebraic varieties. These five constructor use a special kind of characteristic sets, called regular triangular sets. These special characteristic sets have better properties than the general ones. Regular triangular sets and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The decomposition algorithm (due to the third author) available in the four above constructors provide generally better timings than the characteristic set method. In fact, the WUTSET constructor remains interesting for the purpose of manipulating characteristic sets whereas the other constructors are more convenient for solving polynomial systems.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

++ [1] W. T. WU "A Zero Structure Theorem for polynomial equations solving"
++     MM Research Preprints, 1987.
++ [2] D. M. WANG "An implementation of the characteristic set method in Maple"
++     Proc. DISCO'92. Bath, England.
++ Description:
++ A domain constructor of the category \axiomType{GeneralTriangularSet}.
++ The only requirement for a list of polynomials to be a member of such
++ a domain is the following: no polynomial is constant and two distinct
++ polynomials have distinct main variables. Such a triangular set may
++ not be auto-reduced or consistent. The construct operation
++ does not check the previous requirement. Triangular sets are stored
++ as sorted lists w.r.t. the main variables of their members.
++ Furthermore, this domain exports operations dealing with the
++ characteristic set method of Wu Wen Tsun and some optimizations
++ mainly proposed by Dong Ming Wang.

Exports == TriangularSetCategory(R,E,V,P) with

medialSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
++ \axiom{medialSet(ps,redOp?,redOp)} returns \axiom{bs} a basic set

```

```

++ (in Wu Wen Tsun sense w.r.t the reduction-test \axiom{redOp?})
++ of some set generating the same ideal as \axiom{ps} (with
++ rank not higher than any basic set of \axiom{ps}), if no non-zero
++ constant polynomials appear during the computations, else
++ \axiom{"failed"} is returned. In the former case, \axiom{bs} has to be
++ understood as a candidate for being a characteristic set of \axiom{ps}.
++ In the original algorithm, \axiom{bs} is simply a basic set of \axiom{ps}.
medialSet: LP -> Union($,"failed")
++ \axiom{medialSet(ps)} returns the same as
++ \axiom{medialSet(ps,initiallyReduced?,initiallyReduce)}.
characteristicSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
++ \axiom{characteristicSet(ps,redOp?,redOp)} returns a non-contradictory
++ characteristic set of \axiom{ps} in Wu Wen Tsun sense w.r.t the
++ reduction-test \axiom{redOp?} (using \axiom{redOp} to reduce
++ polynomials w.r.t a \axiom{redOp?} basic set), if no
++ non-zero constant polynomial appear during those reductions,
++ else \axiom{"failed"} is returned.
++ The operations \axiom{redOp} and \axiom{redOp?} must satisfy
++ the following conditions: \axiom{redOp?(redOp(p,q),q)} holds
++ for every polynomials \axiom{p,q} and there exists an integer
++ \axiom{e} and a polynomial \axiom{f} such that we have
++ \axiom{init(q)^e*p = f*q + redOp(p,q)}.
characteristicSet: LP -> Union($,"failed")
++ \axiom{characteristicSet(ps)} returns the same as
++ \axiom{characteristicSet(ps,initiallyReduced?,initiallyReduce)}.
characteristicSerie : (LP,((P,P)->B),((P,P)->P)) -> List $
++ \axiom{characteristicSerie(ps,redOp?,redOp)} returns a list \axiom{lts}
++ of triangular sets such that the zero set of \axiom{ps} is the
++ union of the regular zero sets of the members of \axiom{lts}.
++ This is made by the Ritt and Wu Wen Tsun process applying
++ the operation \axiom{characteristicSet(ps,redOp?,redOp)}
++ to compute characteristic sets in Wu Wen Tsun sense.
characteristicSerie: LP -> List $
++ \axiom{characteristicSerie(ps)} returns the same as
++ \axiom{characteristicSerie(ps,initiallyReduced?,initiallyReduce)}.

Chapter X

25.1 domain XDPOLY XDistributedPolynomial

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructor **XDistributedPolynomial** provide a distributed representation for these polynomials. It is the non-commutative equivalent for the **DistributedMultivariatePolynomial** constructor.

++ Keywords:
++ References:
++ Description:
++ This domain constructor implements polynomials in non-commutative
++ variables written in the Poincare-Birkhoff-Witt basis from the
++ Lyndon basis.
++ These polynomials can be used to compute Baker-Campbell-Hausdorff
++ relations.

=====
XPolynomial examples
=====

```

The XPolynomial domain constructor implements multivariate polynomials whose set of variables is Symbol. These variables do not commute. The only parameter of this constructor is the coefficient ring which may be non-commutative. However, coefficients and variables commute. The representation of the polynomials is recursive. The abbreviation for XPolynomial is XPOLY.

Other constructors like XPolynomialRing, XRecursivePolynomial as well as XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPOLY domain constructor.

Define a polynomial ring over the integers.

```
poly := XPolynomial(Integer)
      XPolynomial Integer
                                     Type: Domain
```

Define a first polynomial,

```
pr: poly := 2*x + 3*y-5
      - 5 + x 2 + y 3
                                     Type: XPolynomial Integer
```

and a second one.

```
pr2: poly := pr*pr
      25 + x(- 20 + x 4 + y 6) + y(- 30 + x 6 + y 9)
                                     Type: XPolynomial Integer
```

Rewrite pr in a distributive way,

```
pd := expand pr
      - 5 + 2x + 3y
                                     Type: XDistributedPolynomial(Symbol,Integer)
```

compute its square,

```
pd2 := pd*pd
      25 - 20x - 30y + 4x 2 + 6x y + 6y x + 9y 2
                                     Type: XDistributedPolynomial(Symbol,Integer)
```

and checks that:

```
expand(pr2) - pd2
      0
                                     Type: XDistributedPolynomial(Symbol,Integer)
```

We define:

```
qr := pr**3
      - 125 + x(150 + x(- 60 + x 8 + y 12) + y(- 90 + x 12 + y 18))
      +
      y(225 + x(- 90 + x 12 + y 18) + y(- 135 + x 18 + y 27))
                                     Type: XPolynomial Integer
```

and:

```
qd := pd**3
      - 125 + 150x + 225y - 60x 2 - 90x y - 90y x - 135y 2 + 8x 3 + 12x 2 y + 12x y 2
      +
      2 2 2 3
```

```

18x y  + 12y x  + 18y x y + 18y x + 27y
Type: XDistributedPolynomial(Symbol,Integer)

```

We truncate qd at degree 3.

```

trunc(qd,2)
      2      2
- 125 + 150x + 225y - 60x  - 90x y - 90y x - 135y
Type: XDistributedPolynomial(Symbol,Integer)

```

The same for qr:

```

trunc(qr,2)
- 125 + x(150 + x(- 60) + y(- 90)) + y(225 + x(- 90) + y(- 135))
Type: XPolynomial Integer

```

We define:

```

Word := OrderedFreeMonoid Symbol
OrderedFreeMonoid Symbol
Type: Domain

```

and:

```

w: Word := x*y**2
      2
      x y
Type: OrderedFreeMonoid Symbol

```

We can compute the right-quotient of qr by r:

```

rquo(qr,w)
      18
Type: XPolynomial Integer

```

and the shuffle-product of pr by r:

```

sh(pr,w::poly)
x(x y y 4 + y(x y 2 + y(- 5 + x 2 + y 9))) + y x y y 3
Type: XPolynomial Integer

```

=====

XPolynomialRing examples

=====

The XPolynomialRing domain constructor implements generalized polynomials with coefficients from an arbitrary Ring (not necessarily commutative) and whose exponents are words from an arbitrary OrderedMonoid (not necessarily commutative too). Thus these polynomials are (finite) linear combinations of words.

This constructor takes two arguments. The first one is a Ring and the second is an OrderedMonoid. The abbreviation for XPolynomialRing is XPR.

Other constructors like XPolynomial, XRecursivePolynomial, XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPR domain constructor.

Define the free ordered monoid generated by the symbols.

```

Word := OrderedFreeMonoid(Symbol)
OrderedFreeMonoid Symbol
Type: Domain

```

Define the linear combinations of these words with integer coefficients.

```
poly:= XPR(Integer,Word)
      XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
                        Type: Domain
```

Then we define a first element from poly.

```
p:poly := 2 * x - 3 * y + 1
      1 + 2x - 3y
                        Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

And a second one.

```
q:poly := 2 * x + 1
      1 + 2x
                        Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

We compute their sum,

```
p + q
      2 + 4x - 3y
                        Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

their product,

```
p * q
      1 + 4x - 3y + 4x2 - 6y x
                        Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

and see that variables do not commute.

```
(p+q)**2-p**2-q**2-2*p*q
      - 6x y + 6y x
                        Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

Now we define a ring of square matrices,

```
M := SquareMatrix(2,Fraction Integer)
      SquareMatrix(2,Fraction Integer)
                        Type: Domain
```

and the linear combinations of words with these matrices as coefficients.

```
poly1:= XPR(M,Word)
      XPolynomialRing(SquareMatrix(2,Fraction Integer),OrderedFreeMonoid Symbol)
                        Type: Domain
```

Define a first matrix,

```
m1:M := matrix [ [i*j**2 for i in 1..2] for j in 1..2]
```

```

+1 2+
|   |
+4 8+

```

Type: SquareMatrix(2,Fraction Integer)

a second one,

```

m2:M := m1 - 5/4
+ 1 +
|- - 2 |
| 4 |
|   |
|   27|
| 4 --|
+   4+

```

Type: SquareMatrix(2,Fraction Integer)

and a third one.

```

m3: M := m2**2
+129 +
|--- 13 |
| 16 |
|   |
|   857|
|26 ---|
+   16+

```

Type: SquareMatrix(2,Fraction Integer)

Define a polynomial,

```

pm:poly1 := m1*x + m2*y + m3*z - 2/3
+ 2 + + 1 + +129 +
|- - 0 | |- - 2 | |--- 13 |
| 3 | +1 2+ | 4 | | 16 |
|   | + | |x + | |y + | |z
|   2| +4 8+ | 27| | 857|
| 0 - -| | 4 --| |26 ---|
+   3+ +   4+ +   16+
Type: XPolynomialRing(SquareMatrix(2,Fraction Integer),
OrderedFreeMonoid Symbol)

```

a second one,

```

qm:poly1 := pm - m1*x
+ 2 + + 1 + +129 +
|- - 0 | |- - 2 | |--- 13 |
| 3 | | 4 | | 16 |
|   | + | |y + | |z
|   2| | 27| | 857|

```

```

      | 0  - -|  | 4  --|  |26  ---|
      +      3+  +      4+  +      16+
Type: XPolynomialRing(SquareMatrix(2,Fraction Integer),
OrderedFreeMonoid Symbol)

```

and the following power.

```

qm**3
+ 8      + + 1 8+  +43 52 +  + 129      +

```

Polynomial arithmetic with non-commutative variables has been improved by a contribution

of Michel Petitot (University of Lille I, France). The domain constructors **XRecursivePolynomial** provides a recursive for these polynomials. It is the non-commutative equivalents for the **SparseMultivariatePolynomial** constructor.

28.3 DFLOAT.lsp BOOTSTRAP

DFLOAT depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **DFLOAT** category which we can write into the **MID** directory. We compile the lisp code and copy the **DFLOAT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— DFLOAT.lsp BOOTSTRAP —

28.4 ILIST.lsp BOOTSTRAP

ILIST depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ILIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **ILIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ILIST.lsp BOOTSTRAP —

28.5 INT.lsp BOOTSTRAP

INT depends on **OINTDOM** which depends on **ORDRING** which depends on **INT**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **INT** category which we can write into the **MID** directory. We compile the lisp code and copy the **INT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

28.6 ISTRING.lsp BOOTSTRAP

ISTRING depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ISTRING** category which we can write into the **MID** directory. We compile the lisp code and copy the **ISTRING.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ISTRING.lsp BOOTSTRAP —

28.7 LIST.lsp BOOTSTRAP

LIST depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **LIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **LIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

28.9 OUTFORM.lsp BOOTSTRAP

OUTFORM depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **OUTFORM** category which we can write into the **MID** directory. We compile the lisp code and copy the **OUTFORM.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

28.14 SYMBOL.lsp BOOTSTRAP

SYMBOL depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **SYMBOL** category which we can write into the **MID** directory. We compile the lisp code and copy the **SYMBOL.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— SYMBOL.lsp BOOTSTRAP —

28.15 VECTOR.lsp BOOTSTRAP

VECTOR depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **VECTOR** category which we can write into the **MID** directory. We compile the lisp code and copy the **VECTOR.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.
